SHORT-ACTING BENZODIAZEPINES

Field of the Invention

The present invention relates to benzodiazepine derivatives, to pharmaceutical compositions containing them and to their use in medicine. More particularly, the present invention relates to benzodiazepine derivatives suitable for therapeutic purposes, including sedative-hypnotic, anxiolytic, muscle relaxant and anticonvulsant purposes.

Background of the Invention

The broad neuropharmacology elicited from the benzodiazepine class of compounds is generally attributed to their binding to a site on a specific receptor/chloride ion channel complex known as the GABA_A receptor. Benzodiazepine-receptor binding potentiates the binding of the inhibitory neurotransmitter γ -aminobutyric acid (GABA) to the complex, thereby leading to inhibition of normal neuronal function. In addition to the therapeutic purposes listed above, benzodiazepines have been used widely for anesthesia, particularly as a premedication or as a component in the induction and/or maintenance of anesthesia. See generally, *Goodman and Gilman's The Pharmacological Basis of Therapeutics, Eighth Edition*; Gilman, A. G.; Rall, T. W.; Nies, A. S.; Taylor, P., Eds.; Pergamon Press: New York, 1990; pp. 303-304, 346-358.

Shorter-acting benzodiazepines that may provide faster recovery profiles have been the subject of recent clinical investigations (W. Hering et al., *Anesthesiology* 1996, 189, 85 (Suppl.); J. Dingemanse et al., *Br. J. Anaesth.* 1997, 79, 567-574.) Recent patent filings also describe benzodiazepines of interest. (WO 96/23790; WO 96/20941; US Patent 5,665,718). Other publications that describe benzodiazepinones include E. Manghisi and A. Salimbemi, *Boll. Chim. Farm.* 1974, 113, 642-644), W. A. Khan and P. Singh, *Org. Prep. Proc. Int.* 1978, 10, 105-111 and J. B. Hester, Jr, et al. *J. Med. Chem.* 1980, 23, 643-647. Benzodiazepines in present practice, such as diazepam, lorazepam, and midazolam all undergo metabolism by hepatic-dependent processes. Active metabolites, which are often much more slowly metabolized than the parent drug, can be generated by these hepatic mechanisms in effect prolonging

the duration of action of many benzodiazepines (T. M. Bauer *et al.*, *Lancet* 1995, 346, 145-7). Inadvertent oversedation has been associated with the use of benzodiazepines (A. Shafer, *Crit Care Med* 1998, 26, 947-956), particularly in the ICU, where benzodiazepines, such as midazolam, enjoy frequent use. However, the 5 benzodiazepine compounds of this invention differ from benzodiazepines in present-day clinical practice.

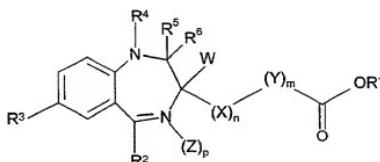

Summary of the Invention

It has now been found that compounds of the present invention as described in Formula (I) possess certain advantages because of their structural design. The benzodiazepines described by this invention all contain a carboxylic ester moiety and are inactivated by nonspecific tissue esterases. An organ-independent elimination mechanism is predicted to be characteristic of the benzodiazepines of this invention, providing a more predictable and reproducible pharmacodynamic profile.

The compounds of the present invention are suitable for therapeutic purposes, including sedative-hypnotic, anxiolytic, muscle relaxant and anticonvulsant purposes. The compounds of the present invention are short-acting CNS depressants that are useful to be administered intravenously in the following clinical settings: preoperative sedation, anxiolysis, and amnestic use for perioperative events; conscious sedation during short diagnostic, operative or endoscopic procedures; as a component for the induction and maintenance of general anesthesia, prior and/or concomitant to the administration of other anesthetic agents; ICU sedation.

Compounds of general formula (I) may be prepared by methods known in the art of organic synthesis as set forth in part by the following synthesis schemes. In all of the schemes described below, it is well understood that protecting groups for sensitive or reactive groups are employed where necessary in accordance with general

principles of chemistry. Protecting groups are manipulated according to standard methods of organic synthesis (T. W. Green and P. G. M. Wuts (1991) Protecting Groups in Organic Synthesis, John Wiley & Sons). These groups are removed at a convenient stage of the compound synthesis using methods that are readily apparent to those skilled in the art. The selection of processes as well as the reaction conditions and order of their execution shall be consistent with the preparation of compounds of Formula I. Those skilled in the art will recognize that a stereocenter exists in compounds of Formula I. Accordingly, the present invention includes both possible stereoisomers and includes not only racemic compounds but the individual enantiomers as well. When a compound is desired as a single enantiomer, it may be obtained by stereospecific synthesis or by resolution of the final product or any convenient intermediate. Resolution of the final product, an intermediate, or a starting material may be effected by any suitable method known in the art. See, for example, Stereochemistry of Organic Compounds by E. L. Eliel, S. H. Wilen, and L. N. Mander (Wiley-Interscience, 1994).

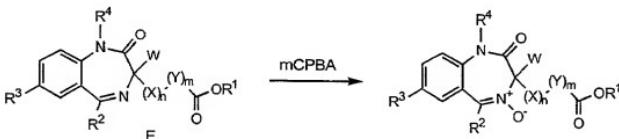

Compounds of Formula (Ia, wherein X = CH₂, R⁴ = H, R⁵ and R⁶ = O, p = 0) can be prepared according to the synthetic sequence shown in Scheme 1a and further detailed in the Examples section (*vide infra*). An appropriate aminobenzophenone (A) is coupled to a suitably protected (e.g., FMOC) amino acid chloride (B) in a suitable solvent, e.g., chloroform, to provide amide (C) (*J. Org. Chem.* 1986, 51, 3732-3734). Carbodiimide-mediated coupling (such as with DCC or EDC) can also be used for this condensation. Base-mediated removal of the amine protecting group (e.g., triethylamine, DCM) and subsequent cyclization (acetic acid, DCE) provides (D), which are compounds of formula Ia wherein R⁵ and R⁶ together represent O for compounds wherein R⁴ is a substituent other than hydrogen, the anilide nitrogen can be alkylated by deprotonation with a base such as NaH in a suitable solvent (e.g. DMF), followed by addition of an alkylating agent such R⁴I, thereby providing the N-alkylated compounds (E), which are also represented by formula (Ia).

SCHEME 1a

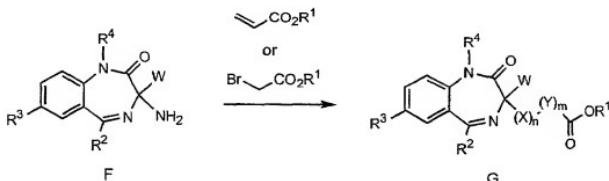

5 N4-oxide derivatives of compounds of Formula (I) ($Z = O$, $p = 1$) can be prepared from compounds of formula (1a) wherein p is zero according to the synthetic sequence shown in Scheme 1b. It is readily apparent to one skilled in the art that benzodiazepinones represented by structure (E) can be oxidized by treatment with mCPBA or other oxidant in a suitable solvent (e.g., DCM).

SCHEME 1b

Compounds of Formula Ia wherein X is NH and p = 0 may be prepared from the appropriate 3-aminoimidazepine F, which can be readily prepared by methods previously described (R. G. Sherrill *et al.*, *J. Org. Chem.* 1995, 60, 730). The 3-amino-1,4-imidazepine thus obtained can be manipulated according to the sequence set forth in Scheme 2 and further detailed in the Examples section (*vide infra*). Alkylation of the 3-amino can be achieved by treatment with a 2-haloacetate (e.g. 2-bromoacetate) or conjugate addition to an appropriate unsaturated ester (e.g. methyl acrylate), providing derivatives G.

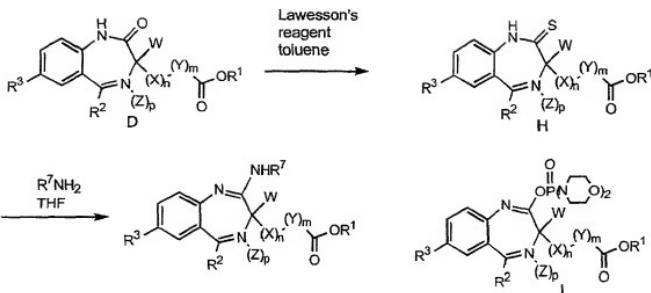

SCHEME 2

Compounds of Formula Ia (wherein R⁵R⁶ = O) can be converted to their corresponding wherein R⁵R⁶ = S with Lawesson's reagent in toluene or other suitable solvent (*J. Org. Chem.* 1964, 29, 231-233).

Compounds of formula Ib may be synthesized as shown in Scheme 3 and further detailed in the Examples section (*vide infra*). Thus reaction of a compound of formula (Ia) wherein R⁴ is hydrogen, R⁵R⁶ = O and p is zero (D) with Lawesson's reagent as described above gives the thiolactam (H).

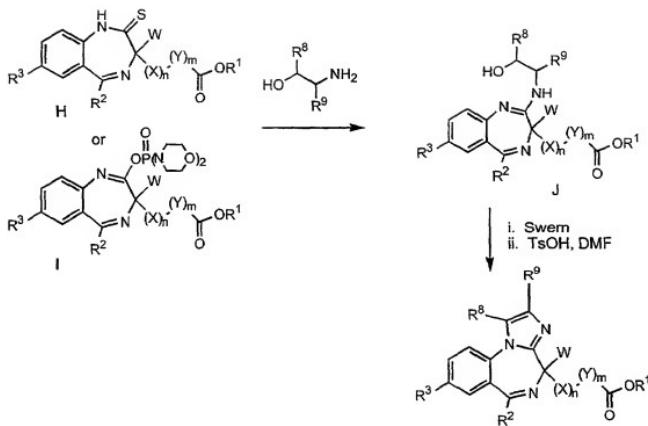

SCHEME 3

Condensation of the thiolactam (**H**) with an amine R⁷NH₂ in tetrahydrofuran affords the corresponding compounds of Formula (1b). Alternatively, compounds of Formula (1b) can be prepared by addition of an amine R⁷NH₂ to the iminophosphate (**I**) in THF, which is prepared by reaction of compound (**D**) with an appropriate phosphoryl chloride reagent, preferably the bis-morpholinophosphoryl chloride (Ning et al., J. Org. Chem. 1976, 41, 2720-2724; Ning et al., J. Org. Chem. 1976, 41, 2724-2727).

A method of preparation of compounds of formula (1c; U = CR⁹; V = N), is set forth in Scheme 4 and further detailed in the Examples section (*vide infra*).

SCHEME 4

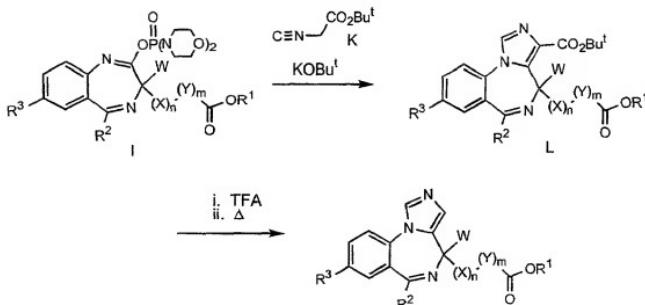

These methods are analogous to those described (WO 96/20941, WO

96/23790). Reaction between either the thiolactam (**H**) or iminophosphate (**I**) and an appropriate an amino alcohol $\text{HOCH}(\text{R}^8)-\text{CH}(\text{R}^9)\text{NH}_2$ provides adduct (**J**). Swern oxidation (i. DMSO, TFAA or COCl_2 ; TEA) of the hydroxyl group provides an intermediate ketone or aldehyde that undergoes cyclodehydration, spontaneously or under appropriate acidic conditions (e.g. p-toluenesulfonic acid, DMF), to provide compounds of formula (1c; $U = \text{CR}^9$; $V = \text{N}$).

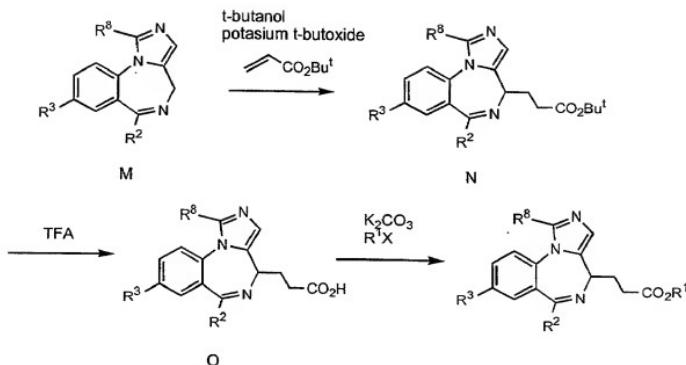

As set forth in Scheme 5, reaction of (**I**) (*J. Med. Chem.* 1993, 36, 479-490; *J. Med. Chem.* 1993, 36, 1001-1006) with the anion of isonitrile ester (**K**) delivers imidazole (**L**) as the product; subsequent removal of the ester functionality by methods set forth in the examples (*vide infra*) provides compounds of formula 1c; $U = \text{N}$; $V = \text{CH}$.

SCHEME 5

An alternative method for the preparation of compounds of formula (1c; wherein X is CH₂, n is Z, m = 0, U = N; V = CH), is set forth in Scheme 6 and further detailed in the Examples section (*vide infra*). C4-unsubstituted imidazobenzodiazepine (M) is treated with a strong base (preferably potassium t-butoxide) and the anion is treated with a suitable Michael acceptor, such as t-butyl acrylate. The resultant ester adduct (N) is treated with a strong acid (e.g., TFA) to remove the t-butyl group and the carboxylic acid (O) is esterified to provide compounds of Formula (1c) by base-mediated alkylation with an alkyl halide.

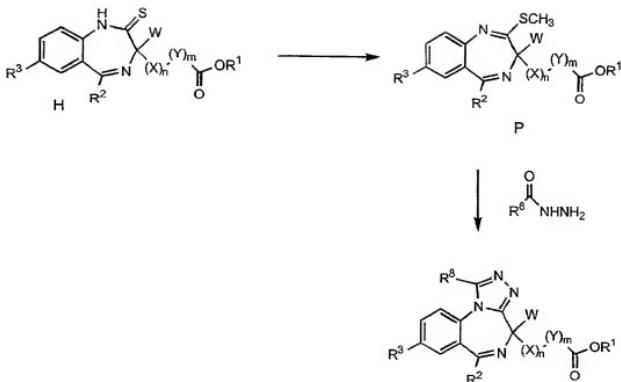

SCHEME 6

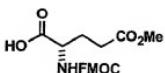

Alternative methods to prepare these compounds have also been described (e.g., *J. Org. Chem.* **1978**, *43*, 936-944).

Compounds of formula 1c ($U = N$; $V = N$), may be prepared as set forth in Scheme 7 and further detailed in the Examples section (*vide infra*). Thiolactam (**H**) is converted to its corresponding methylthioimidate (**P**), which then undergoes condensation and cyclodehydration to provide the desired triazolobenzodiazepine.

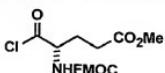

SCHEME 7

Synthesis of Key Intermediates

The following section describes the preparation of intermediates that may be used in the synthesis of compounds of Formula I. There may be examples wherein the starting material can be prepared according to the methods set forth in the synthesis of an intermediate. It should be readily apparent to one skilled in the art how these methods can be applied to include all compounds of Formula I.

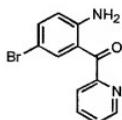

The synthesis of the FMOC-Glu(OMe)-OH was carried out as described in *Int. J. Peptide Protein Res.* 1989, 33, 353.

Intermediate-1 (Int-1)

FMOC-Glu(OMe)-OH (80 g, 0.21 mol) was dissolved in CH₂Cl₂ (523 mL). DMF (1 mL) was added followed by dropwise addition of oxalyl chloride (19 mL, 0.22 mol). The solution was stirred at room temperature for 4 h, and concentrated *in vacuo* to a volume of ca. 200 mL. To this stirring concentrate was added hexanes by rapid dropwise addition. The resulting slurry was stirred for 30 min and filtered to provide the required acid chloride as a white solid (83 g, 98%).

5 **Int-2**

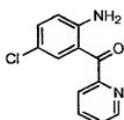

To a -40°C solution of 2.5 M n-butyllithium in hexane (400 mL, 1000 mmol, 4 eq) and diethyl ether (1 L) was added 2-bromopyridine (173.93 g, 1101 mmol, 4.4 eq) over approximately 30 min. The reaction was stirred for 1 h at -40°C, and then treated with 5-bromoanthranilic acid (54.14 g, 250.6 mmol, 1 eq) in THF (1 L). The reaction was warmed to 0°C and stirred 2 h at 0°C, then quenched with chlorotrimethylsilane (625 mL, 4924 mmol, 20 eq). The reaction was stirred 30 min at ambient temperature, then cooled to 0°C and quenched with 3N HCl (625 mL). The aqueous layer was separated, and the organic layer was extracted once with 3N HCl. The combined aqueous layers were neutralized with solid sodium hydroxide pellets, with cooling via ice bath. The resulting mixture was extracted with diethyl ether (3 × 1 L). The combined ether layers were dried over sodium sulfate, filtered and concentrated to a black oil, which was subsequently purified by flash chromatography (1 L silica gel, 20-30% ethyl acetate/hexane) to give the required compound as a brown solid (62 g, 224 mmol, 89.3%).

5 *tert*-Butyllithium (43.4 mL of a 1.7 M solution in pentane, 73.8 mmol) was added to a solution of N-BOC-4-chloroaniline (7.00 g, 30.8 mmol) in THF (154 mL) at -78 °C. The reaction mixture was stirred for 15 min then warmed to -20 °C and stirred an additional 2 h. The reaction mixture was cooled to -78 °C, treated with 2-pyridinecarboxaldehyde (2.92 mL, 30.8 mmol), stirred for 2 h, treated with saturated aqueous NaHCO₃ (ca. 50 mL), and warmed to room temperature. The mixture was concentrated under reduced pressure and the residue was extracted with EtOAc (1 x 500 mL). The organic phase was washed with saturated aqueous NaHCO₃ (1 x 100 mL), H₂O (1 x 100 mL), saturated aqueous NaCl (1 x 100 mL), dried (Na₂SO₄), and concentrated under reduced pressure. The residue was dissolved in CHCl₃ (150 mL), treated with activated MnO₂ (58% by weight, 30.0 g, 200 mmol), and stirred for 18 h. The reaction mixture was filtered through a pad of Celite using additional CHCl₃ (ca. 100 mL) and the filtrate was concentrated under reduced pressure. Purification by flash chromatography, elution with 9:1 hexane-EtOAc, gave 6.02 g (59%) of the intermediate BOC-protected aminobenzophenone as a foam.

20 A solution of the BOC-protected aminobenzophenone described above (5.93 g, 17.8 mmol) and HCl (18.0 mL of a 4M solution in 1,4-dioxane, 71.3 mmol) in CH₂Cl₂ was stirred for 4 h at room temperature then concentrated under reduced pressure. The residue was diluted with EtOAc (ca. 200 mL) and treated with saturated aqueous NaHCO₃ until CO₂ evolution ceased. The layers were separated and the organic phase was washed with saturated aqueous NaHCO₃ (1 x 50 mL), H₂O (1 x 50 mL), saturated aqueous NaCl (1 x 50 mL), dried (Na₂SO₄), and concentrated under reduced pressure to give 3.83 g (92%) of the title compound as a yellow amorphous solid; ¹H NMR (400 MHz, DMSO-*d*₆) δ 8.68 (d, J = 4.6 Hz, 1H), 8.02 (ddd, J = 7.8, 7.8, 1.6 Hz, 1H), 7.78 (d, J = 7.8 Hz, 1H), 7.59 (m, 1 H), 7.52 (d, J = 2.6

The reaction mixture was concentrated under reduced pressure and the residue was dissolved in EtOAc (ca. 250 mL), washed with saturated aqueous NaHCO₃ (2 x 50 mL), H₂O (1 x 50 mL), brine (1 x 50 mL), dried (Na₂SO₄) and concentrated under reduced pressure to give 1.91 g (99%) of the trifluoracetanilide.

10 A mixture of KNO₃ (905 mg, 8.96 mmol) in concentrated H₂SO₄ (12 mL) was added to a mixture of amide (1.76 g, 5.97 mmol) in concentrated H₂SO₄ (18mL) maintaining the reaction temperature at ≤ 16 °C with an ice bath. The reaction mixture was allowed to warm to room temperature, stirred 4 h, and poured onto ice (ca. 150 g). The mixture was neutralized by slow addition of 25% aqueous NaOH (ca. 175 mL) maintaining the temperature at ≤ 18 °C with an ice bath. The aqueous layer was extracted with EtOAc (2 x 200 mL). The combined organic extracts were washed with H₂O (1 x 100 mL), brine (1 x 100 mL), dried (Na₂SO₄) and concentrated under reduced pressure to give a solid. The silica gel was slurried in CH_2Cl_2 , filtered, and the filtrate was concentrated under reduced pressure to give a yellow viscous oil. Ether was added to the oil to precipitate a pale yellow solid that was filtered, washed with several additional portions of ether, and dried *in vacuo* to provide 11.47 g (65%) of I-28 as a yellow solid. ^1H NMR (CDCl_3 , 300 MHz) δ 10.1 (br s, 1H), 7.60 (t, 1H, J = 7.4 Hz), 7.51 (m, 2H), 7.21 (m, 2H), 7.19 (d, 1H, J = 8.4 Hz), 7.15 (t, 1H, J = 9.3 Hz), 3.95 (m, 1H), 3.69 (s, 3H), 2.86 (m, 1H), 2.68 (m, 3H).

Synthesis of Compounds of Formula Ib

Compounds of formula (1b) may be prepared from the corresponding thiolactam of formula (1a) wherein R⁴ is hydrogen and R⁵, R⁶ = S) by the following general methods.

General Procedure I: The addition of amines to thiolactam to produce amidines.

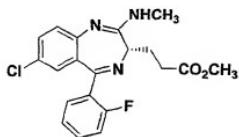

The Thiolactam, the appropriate amine (5-20 mmol/mmol of thiolactam), and either tetrahydrofuran (THF, 2-10 mL/mmol of thiolactam) or 1,4-dioxane (dioxane, 2-10 mL/mmol of thiolactam) were combined and heated to 50 °C (THF) or 95 °C (dioxane) for 2-72 h. When the reaction was judged by TLC to be complete, the

reaction mixture was allowed to cool to RT. The solvents were removed *in vacuo* and, in some cases, the residue was directly chromatographed on silica gel to provide the desired amidine. In other cases, the remaining residue was dissolved in an appropriate solvent (EtOAc, for example) and the product was washed with H₂O, brine, dried (MgSO₄ or CaSO₄), filtered and the solvents were again removed under reduced pressure and the residue was chromatographed on silica gel to provide the desired amidine of Formula Ib.

The following compounds were prepared according to the general procedure above. Any modifications in starting materials or conditions that are required for the synthesis of a particular example will be readily apparent to one skilled in the art of organic synthesis.

Synthesis of Compounds of Formula Ic**General Procedure I: Swern oxidation of Alcohols using oxalyl chloride as activating agent.**

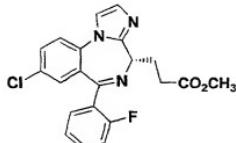

A round-bottom flask was equipped with a stir bar and flushed with N₂. To the flask were added CH₂Cl₂ (5-15 mL/mmol of alcohol), dry dimethyl sulfoxide (DMSO, 3-4 mmol/mmol of alcohol) and the solution was cooled to -78 °C by means of a dry ice/acetone bath. Oxalyl chloride (2-3 mmol/mmol of alcohol) was added dropwise to the DMSO solution, taking care to maintain the reaction temperature below -50 °C. When the addition was complete, the resulting solution was allowed to stir at -78 °C for 30 min. The Alcohol was dissolved in CH₂Cl₂ (2-3 mL/mmol of alcohol) and was carefully added to the DMSO solution at -78 °C. The resulting mixture was allowed to stir at -78 °C for 2 h. Triethylamine (5-11 mmol/mmol of alcohol) was added and the mixture was allowed to warm to RT. When the reaction was judged to be complete, the mixture was poured into a separatory funnel containing water and CH₂Cl₂. The organic layer was collected and was washed with water, saturated aqueous brine, dried over Na₂SO₄, filtered and the solvents were removed under reduced pressure to provide the desired product which, in most cases, was used without further purification. If deemed necessary, the product was further purified by flash chromatography on silica gel.

General Procedure II: Swern oxidation of Alcohols using trifluoroacetic anhydride as activating agent.

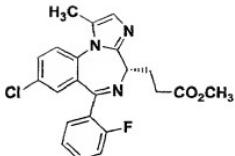

Anhydrous DMSO (3-4 mmol/mmol of alcohol) was added to CH₂Cl₂ (5-15 mL/mmol of alcohol) and the solution was cooled to -78 °C. Trifluoroacetic anhydride (2-3 mmol/mmol of alcohol) was added dropwise to the DMSO solution, taking care to maintain the reaction temperature below -50 °C. When the addition was complete, the resulting solution was stirred at -78 °C for 30 min. A solution of the Alcohol in CH₂Cl₂ (2-3 mL/mmol of alcohol) was added carefully to the DMSO solution at -78 °C. The reaction mixture was allowed to stir at -78 °C for 2 h, after which time it was allowed to warm to -35 °C for 5 min and was again cooled to -78 °C. Et₃N (5-10 mmol/mmol of alcohol) was added and the stirring was continued at -

78 °C for 30 min, after which time the reaction mixture was allowed to warm to RT. When the reaction was judged to be complete, the mixture was poured into a separatory funnel containing H₂O and CH₂Cl₂ and the layers were separated. The organic layer was washed with H₂O, brine, dried (MgSO₄), filtered and the solvents were removed under reduced pressure to provide the desired product which, in most cases, was used without further purification. If deemed necessary, the product was purified by flash chromatography on silica gel.

Moreover, while it is possible for the compounds of the invention to be administered as the bulk active chemicals, it is preferably presented with an acceptable carrier in the form a pharmaceutical formulation. Accordingly, the present invention provides a pharmaceutical formulation which comprises a compound of Formula (I) as hereinbefore defined and a pharmaceutically acceptable carrier in the form a pharmaceutical formulation. The formulations include those suitable for oral, rectal, topical, buccal (e.g. sub-lingual) and parenteral (e.g., subcutaneous, intramuscular, intradermal or intravenous) administration. Intravenous administration can take the form of bolus injection or, more appropriately, continuous infusion. The dosage for each subject may vary, however, a suitable intravenous amount or dosage of the compounds of the present invention to obtain sedation or hypnosis in mammals would be 0.01 to 5.0 mg/kg of body weight, and more particularly, 0.02 to 0.5 mg/kg of body weight, the above being based on the weight of the compound which is the active ingredient. A suitable intravenous amount or dosage of the compounds of the present invention to obtain anxiolysis in mammals

The compounds of the present invention elicit important and measurable pharmacological responses. The compounds described by this invention bind with high affinity to the benzodiazepine site on the GABA_A receptor complex ("benzodiazepine receptor"). The binding affinity was measured by use of the following benzodiazepine radioligand binding assay.

Tissues: Membrane homogenates were prepared from male Sprague Dawley rat brain (whole brain less cerebellum), female Yucatan micropig brain cortex and female human brain cortex according to the methods described by Marangos & Martinos (Molecular Pharmacology 20:16-21, 1981). The human donor was a 72 year old female Caucasian who died of an acute cardiopulmonary aneurysm. All tissues were obtained from, and membrane homogenates were prepared by Analytical Biological Services (ABI, Wilmington, DE). Homogenates were frozen, stored at minus 80°C and thawed immediately before use in radioligand binding assays.

Materials: ³H-flunitrazepam (NET-567) was obtained from New England Nuclear, Boston, MA. 2'-chlorodiazepam was prepared at Glaxo Wellcome, RTP, USA. Tris HCl was obtained from GibcoBRL and sodium chloride was obtained from J.T. Baker. Microscint-20 liquid scintillant and Unifilter 96 well plates were

purchased from Packard Instruments. Midazolam and chlordiazepoxide were purchased from Sigma Chemicals. Flumazenil was a gift from Hoffman LaRoche.

Assay conditions: Test compounds were prepared in 100% DMSO at a concentration of 25-50 mM. Compounds were diluted in assay buffer such that the first well contained 100 μ M (final concentration). Eleven 3-fold serial dilutions were prepared in buffer to complete a 12-point concentration-response curve for each test compound. Each concentration was tested in triplicate and compounds of interest were tested on at least 3 separate occasions. The final concentration of DMSO in each well did not exceed 0.4%. Nonspecific binding was defined in the presence of 10 μ M 2'-chlorodiazepam ($K_i = 0.5$ nM). The final concentrations of 3 H-flunitrazepam were 2 nM, 2 nM and 2.5 nM for rat, micropig and human assays, respectively. The concentrations differed slightly among the tissues so that the signal-to-noise ratio was optimized and the lowest possible concentration was used. Concentration-response curves for midazolam, chlordiazepoxide or flumazenil were conducted as controls with each assay run. Radioligand, compounds and membrane homogenates were incubated for 90 minutes at 4°C in buffer consisting of 50 mM Tris HCl, pH 7.4, containing 150 mM NaCl. All assays were conducted in 96 well plates in a total assay volume of 200 μ L. Protein concentrations were 12, 9 and 15 micrograms/well for rat, pig and human preparations, respectively. The reaction was terminated by rapid filtration (Packard Filtermate-196) through 96-well GF/B filter plates (Packard # 6005177). The filters were washed 8 times with 200 μ L/well with ice-cold Tris 50 mM, pH7.4 (~1.6 ml total). After drying, 20 μ L of Microscint was added to each well and the plates were sealed. Plates were counted using a Packard TopCount microliter plate scintillation counter.

Data analysis: Data were analyzed, fitted to a single site equation, and IC_{50} values were calculated using the Excel Addin Robosage (Glaxo Wellcome Research Information Resources). K_i values were calculated using the equation of Cheng and Prusoff (Biochem. Pharmacol. 22:3099-3108, 1973). K_d values of 3 H-flunitrazepam used in K_i calculations were determined for each tissue in saturation binding experiments.

High affinity binding of a ligand to the benzodiazepine receptor does not characterize the intrinsic efficacy (full agonist, inverse agonist, antagonist) of a benzodiazepine receptor ligand. The intrinsic efficacy of a compound was assessed by its ability to cause loss of the righting reflex (LRR) in rats, an effect associated with benzodiazepine full agonism.

Method: Subjects for these studies were male Wistar rats, weighing approximately 250 – 350 grams. To assess loss of righting reflex (LRR), animals were placed in plastic restrainers and test compounds were administered i.v. via the tail vein. Subjects were immediately removed from the restrainer and the time to onset of loss of righting reflex was recorded. LRR was defined as the loss of an animal's ability to right itself when placed in a supine position. A compound was identified as inactive in this model if LRR was not observed within 5 minutes following injection. Compounds producing LRR were evaluated by three measures: 1) Time to onset of LRR (as described above) 2) Time to recover from LRR. An animal met this criteria when able to right itself three consecutive times after losing its righting reflex 3) Total recovery time. Total recovery was measured by the animal's ability to walk without ataxia as well as its ability to pull itself up three consecutive times when suspended from a horizontal wire. Compounds producing loss-of-righting at a dose in the range of 10-100 mg/kg include the following: examples 1, 3, 4, 5, 6, 7, 9, 11, 17, 23 of compounds of Formula Ia, examples 1 and 10 of compounds of Formula Ib and examples 1, 2, 3, 6, 7, 8, 10, 14, 15, 17, 18 of compounds of Formula Ic. In the rat loss-of-righting model at a dose range of 10-100 mg/kg, the compounds of this invention displayed overt pharmacological responses similar to those of therapeutically useful benzodiazepines described in the prior art. The therapeutically useful dosage range for administration to mammals is 0.01 to 5.0 mg/kg of body weight.
